

Assignment report

My first step was identifying which data from the csv file do I need for my tasks and deleting the unnecessary columns. After that I could move on to the coding part. The next step was deciding on which way should I approach in implementing the solutions in the task - whether to write everything in one class or divide it into multiple classes for better organization. Finally, I started with writing the code. The most challenging part was learning things I never did before. For example, splitting data and handling with multiple commas and quotes were one of it. I explored about regex and patterns (with the help of resources like Claude.ai). While regex seemed simple at first, it was confusing to understand and remember. Then I found a method which was understandable and also a little bit more complexed than regex. After overcoming this obstacle, other things were simpler. I expected that tasks 6 and 7 would be so much harder than they are. Finding titles with only one word sounded complex but after `.trim` and checking if the title contains blank space, the solution was straightforward. Similarly with finding shows where first air data and last air data were between 1st January 2010 and 31st December 2019, was simpler than expected once I discovered Java's built-in possibilities for date patterns. On the other hand, the thing which was more complex than I expected was overcoming errors and debugging. Although Java has a great option which checks for bugs and errors, finding what really produces the errors and implementing solutions for them was little complicated. If I were to start the assignment again, I would surely try to make the code cleaner and write functions instead of copying the same code few times over the classes. This would make the code easier to read and understand for others. All in all, the assignment was more challenging than I thought but after spending few hours researching and learning new things, everything was more clear and it made sense.
